

Arrays (1D, 2D)

Def: An array stores multiple values of the same type together under one variable name, in a fixed-size sequence.

How to use: `int[] marks = {90, 85, 78, 92};` } // 1D Array
S.O.P (marks[0]); // 90

`int[][] grid = {{1, 2}, {4, 5}};` } // 2D Array
S.O.P (grid[1][2]);

When to use: Anywhere you deal with collections of similar data - student records, grids, tables, matrices.

Why arrays instead of separate variables: managing

Date: / /

ASHOKA

marks1, marks2, marks3 --- marks100 is unmanageable.

Arrays let you loop through & process all values with a few lines of code, at any scale.

Real-life example: A 1D array is like an egg tray (single row of slots). A 2D array is like a chocolate box with rows & column no. to find a specific chocolate.
